(Deep Roadmap-Level Notes — With Derivations, Intuition, Code, ML Applications)

This follows your roadmap structure:

From Mathematical Foundations → Calculus:

- Derivatives
- Partial Derivatives
- Chain Rule
- Gradient
- Jacobian
- Hessian

We go FULL depth.

🔷 1. What is Calculus?

📌 Definition

Calculus is the branch of mathematics that studies:

- Change
- Rates of change
- Accumulation

It allows us to understand how functions behave and how to optimize them.

🎯 What It Does in ML

Calculus helps us:

- Minimize loss functions
- Train neural networks
- Update model weights
- Perform gradient descent
- Understand optimization

⚙️ How It Works

It works using:

- Derivatives

- Partial derivatives
- Chain rule
- Gradients
- Higher-order derivatives

🤖 Why It Is Essential in ML

Machine Learning = Optimization problem.

We try to:

$$\min_{\theta} L(\theta)$$

Where:

- $L(\theta)$ = loss function
- θ = parameters

To minimize → we need derivatives.

No calculus → no learning.

🔷 2. Derivatives (Single Variable)

🔹 2.1 Definition

The derivative of a function measures its rate of change.

Mathematically:

$$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$$

🔹 2.2 Intuition

Derivative = slope of tangent line.

If:

- Positive → increasing

- Negative → decreasing
- Zero → critical point

🔹 2.3 Example Derivation

Let:

f(x) = x^2

Using definition:

$$f'(x) = \lim_{h \to 0} \frac{(x+h)^2 - x^2}{h}$$

Expand:

$$= \lim_{h \to 0} \frac{x^2 + 2xh + h^2 - x^2}{h}$$

$$= \lim_{h \to 0} \frac{2xh + h^2}{h}$$

$$= \lim_{h \to 0} (2x + h)$$

$$= 2x$$

So:

$$\frac{d}{dx}(x^2) = 2x$$

🔹 2.4 Why Important in ML?

Loss function example:

$$L(w) = (y - wx)^2$$

Derivative tells how to update weight.

🔹 2.5 Code Example

Explanation:

Approximates:

$$\frac{d}{dx}(x^2) = 6$$

🔷 3. Partial Derivatives (Multivariable Calculus)

🔹 3.1 Definition

If function depends on multiple variables:

$$f(x, y)$$

Partial derivative w.r.t x:

$$\frac{\partial f}{\partial x}$$

Treat other variables constant.

🔹 3.2 Example

$$f(x, y) = x^2 + 3xy + y^2$$

Partial derivative w.r.t x:

$$\frac{\partial f}{\partial x} = 2x + 3y$$

w.r.t y:

$$\frac{\partial f}{\partial y} = 3x + 2y$$

🔹 Why Important?

ML models have many parameters:

$$L(w_1, w_2, ..., w_n)$$

We need partial derivative for each weight.

🔷 4. Gradient (Core of ML)

🔹 4.1 Definition

Gradient = vector of partial derivatives.

$$\nabla f = \begin{bmatrix} \frac{\partial f}{\partial x_1} \\ \frac{\partial f}{\partial x_2} \\ \vdots \end{bmatrix}$$

🔹 4.2 What It Does

Points in direction of steepest increase.

Negative gradient → steepest decrease.

🔹 4.3 ML Application — Gradient Descent

Update rule:

$$\theta = \theta - \alpha \nabla L(\theta)$$

Where:

- α = learning rate

🔹 Code Example

Explanation:

Minimizing:

$$(y - wx)^2$$

🔷 5. Chain Rule (Backpropagation Foundation)

🔹 5.1 Definition

If:

$$z = f(g(x))$$

Then:

$$\frac{dz}{dx} = \frac{dz}{dg} \cdot \frac{dg}{dx}$$

Example

Let:

$$z = (3x^2 + 2)^4$$

Outer function:

$$u^4$$

Inner function:

$$u = 3x^2 + 2$$

Derivative:

$$\frac{dz}{dx} = 4(3x^2 + 2)^3 \cdot 6x$$

Why Important?

Neural networks are nested functions:

$$L = f(W_2 f(W_1 x))$$

Backpropagation uses chain rule repeatedly.

---

6. Jacobian

Definition

For vector function:

$$F(x_1, x_2)$$

Jacobian matrix:

$$J = \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} \end{bmatrix}$$

🔹 Why Important?

Used in:

- Backpropagation
- Vector transformations
- Optimization

🔷 7. Hessian Matrix (Second Derivatives)

🔹 Definition

Matrix of second-order partial derivatives.

$$H = \begin{bmatrix} \frac{\partial^2 f}{\partial x^2} & \frac{\partial^2 f}{\partial x \partial y} \\ \frac{\partial^2 f}{\partial y \partial x} & \frac{\partial^2 f}{\partial y^2} \end{bmatrix}$$

🔹 What It Tells

- Convexity
- Local minima
- Saddle points

If Hessian positive definite → convex.

🔷 8. Convexity & Optimization

🔹 Convex Function

$$f(\lambda x_1 + (1-\lambda)x_2) \leq \lambda f(x_1) + (1-\lambda) f(x_2)$$

Convex → gradient descent works.

Non-convex → multiple minima.

🔷 9. Taylor Series (Approximation)

$$f(x+h) = f(x) + hf'(x) + \frac{h^2}{2} f''(x) + \ldots$$

Used in:

- Optimization
- Newton's Method

🔷 10. Newton's Method

Update rule:

$$\theta = \theta - H^{-1} \nabla L(\theta)$$

Faster but expensive.

🔷 11. Backpropagation (Core ML Concept)

Neural network:

$$Z = WX + b$$

Loss:

$$L = (y - \hat{y})^2$$

Using chain rule:

$$\frac{dL}{dW} = \frac{dL}{d\hat{y}} \cdot \frac{d\hat{y}}{dZ} \cdot \frac{dZ}{dW}$$

That's backpropagation.

🧠 PRACTICE PROBLEMS

🟢 Beginner

1. Find derivative of:

   f(x) = 3x^3 + 2x
2. Compute:

   $\frac{d}{dx}(e^x)$

🟡 Intermediate

3. Find gradient of:

   $f(x, y) = x^2 + y^2 + xy$
4. Derive gradient descent update rule.

🔴 Advanced

5. Prove that gradient is perpendicular to level curves.
6. Derive backpropagation from scratch.
7. Show Hessian positive definite implies convexity.

🎯 INTERVIEW QUESTIONS

---

1. Why do we use gradient descent?

Because derivative tells direction of minimum.

---

2. What happens if learning rate too high?

Divergence.

---

3. Difference between Jacobian and Hessian?

Jacobian → first derivatives matrix

Hessian → second derivatives matrix

---

4. Why is ReLU derivative important?

Avoids vanishing gradient.

---

5. What causes vanishing gradient?

Repeated multiplication of small derivatives.

🚀 FINAL SUMMARY

Linear Algebra → Structure

Calculus → Learning

Together:

$$\text{Machine Learning} = \text{Linear Algebra} + \text{Calculus} + \text{Probability}$$
